2. Typical application circuit

Fig. 3 Application circuits in series and parallel

If it is necessary to protect LED in actual application, you could connect a PTC to the input of every channel or all channels, as shown in Figure 3.
Note: The negative output terminal can't connect GND, or the module may be damaged.

3. PWM dimming control

For a certain frequency of PWM dimming, the output current of the driver is inversely proportional to the duty cycle of the PWM signal. By adjusting the duty cycle of the PWM signal, the brightness of the LED can be adjusted. The formula is:

$$I_{o_set} = I_{o_nom} \times (1-D)$$

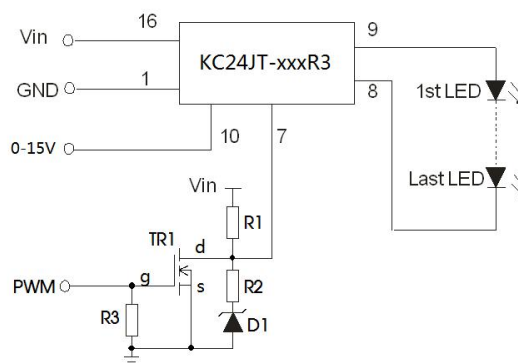

I_{o_set} refers to the wanted output current value.

I_{o_nom} refers to the rated output current

D refers to the pulse width of the PWM signal

For example: we assume the rated output current is 700mA and wanted output current is 350mA, then the pulse width should be 0.5 from the equation above. That is say if we keep the pulse width of PWM signal at 0.5, the output current will be kept at 350mA. It is natural for the driver to generate a audibly noise in dimming process, because the frequency of the control circuit is within human audibly range (20Hz~20KHz). In order to avoid the human eye can observe the LED flashes, the PWM dimming frequency is recommended to set above 100Hz.

R1	8.2k Ω /0.5W
R2/R3	1k Ω /0.5W
TR1 (N type)	40V/2A

For a certain frequency of PWM dimming, the output current of the driver is proportional to the duty cycle of the PWM signal.
